STRESS WAVES IN A MICROPERIODIC LAYERED ELASTIC SOLID REVISITED

JÓZEF IGNACZAK and ELŻBIETA MRÓWKA-MATEJEWSKA

(Received 10 June 2001)

Abstract. A one-dimensional pure stress initial boundary value problem of linear elastodynamics for a microperiodic layered semi-space in which a microstructural length is taken into account is revisited. Also, the plane stress harmonic waves propagating in a microperiodic layered infinite elastic space are discussed. It is shown that (i) for a particular system of the length and time units the transient stress waves in the microperiodic layered semi-space are independent of the microstructural length, and (ii) there are two dispersive plane stress harmonic waves propagating in a microperiodic layered infinite elastic space. The graphs illustrating the transient stress waves in the semi-space and the dispersion of harmonic waves in the infinite space are included.

2000 Mathematics Subject Classification. 74H05, 74H25, 74H45, 74J05, 74Q10.

1. Basic field equations for a microperiodic layered elastic semi-space. Consider a layered semi-infinite elastic solid composed of an infinite number of identical subunits that are mechanically bonded to form a spatially periodic pattern as shown in Figure 1.1. Each subunit consists of two layers that, in general, have different dimensions and are made of different homogeneous isotropic elastic materials. Let \( l_i, \rho_i, \lambda_i, \) and \( \mu_i \) \((i = 1, 2)\), respectively, denote the physical dimension, density, Lamé modulus, and shear modulus of the \( i \)th layer in a subunit. If the interface conditions between any two adjacent layers are assumed to be of an ideal mechanical contact type, that is, the displacement and stress vectors are continuous across an interface, and a mechanical load is uniformly distributed over the boundary \( x = 0 \) for every time \( t \geq 0 \), an elastic process in the layered semi-space can be described by a solution to a one-dimensional initial boundary value problem of classical elastodynamics. In such a problem the field equations of homogeneous isotropic elastodynamics are to be satisfied for each layer and suitable initial, interface, and boundary conditions at \( x = 0 \) and \( x = \infty \) are to be met. Since an exact solution to the problem is not feasible, the classical formulation for the layered semi-space is replaced by the approximate one of a refined average theory (RAT), (see [1, 2, 4]). The field equations of the approximate theory read: the \( h \)-approximation of the displacement field

\[
\begin{align*}
\mathbf{u}(x,t) &= \mathbf{U}(x,t) + h(x)\mathbf{V}(x,t). \\
S_x - \langle \rho \rangle U_{tt} &= 0, & H + \langle \rho h^2 \rangle V_{tt} &= 0.
\end{align*}
\]

The equations of motion

\[ S_x - \langle \rho \rangle U_{tt} = 0, \quad H + \langle \rho h^2 \rangle V_{tt} = 0. \]
The constitutive relations

\[ S = \langle \Lambda \rangle U_x + \langle \Lambda h_x \rangle V, \]
\[ H = \langle \Lambda h_x \rangle U_x + \langle \Lambda h_x^2 \rangle V. \] (1.3)

Here, \( h = h(x) \) is a dimensionless oscillating periodic function on \([0, \infty)\) with period \( l \) that satisfies the conditions

\[ \langle h \rangle = 0, \quad \langle \eta h \rangle = 0, \quad \langle \eta h_x \rangle \neq 0, \] (1.4)

for any function \( \eta = \eta(x) \) on \([0,l]\) of the form

\[ \eta(x) = \begin{cases} \eta_1 & \text{for } 0 \leq x < l_1, \\ \eta_2 & \text{for } l_1 \leq x \leq l, \end{cases} \] (1.5)

where \( \eta_1 \) and \( \eta_2 \) are constants \( \eta_1 \neq \eta_2 \); and for any function \( F = F(x) \) on \([0,l]\) the symbol \( \langle \cdot \rangle \) represents the mean value of \( F \) on \([0,l]\)

\[ \langle F \rangle = \frac{1}{l} \int_0^l F(x) \, dx. \] (1.6)

In addition, the function \( h = h(x) \) satisfies the asymptotic estimate

\[ h(x) = l \, 0(1) \quad \text{as } l \to 0. \] (1.7)

If \( l \) is small, the function \( h = h(x) \) represents a micro-periodic shape function. A typical micro-periodic shape function \( h = h(x) \) restricted to the interval \([0,l]\) is shown in Figure 1.2.

Other symbols in (1.1), (1.2), and (1.3) have the following meaning. In (1.1) the function \( u \) represents a displacement in the \( x \)-direction; \( U \) is a macro-displacement in
the $x$-direction and $V$ is a displacement corrector. In (1.2) and (1.3) the function $S$ is a stress component in the $x$-direction and $H$ is a body force component in the $x$-direction; moreover, $\Lambda = \lambda + 2\mu$, where $\lambda$ and $\mu$ are Lamé moduli, and $\rho$ is the density. The subscripts in (1.2) and (1.3) indicate partial derivatives.

The kinetic energy density $K = K(x,t)$ and the potential energy density $P = P(x,t)$, associated with (1.2) and (1.3) are represented by the functions

$$K(x,t) = \frac{1}{2} \left[ \langle \rho \rangle U_t^2 + \langle \rho h^2 \rangle V_t^2 \right],$$

$$P(x,t) = \frac{1}{2} \left[ \langle \Lambda \rangle U_x^2 + 2 \langle \Lambda h_x \rangle U_x V + \langle \Lambda h_x^2 \rangle V^2 \right],$$

respectively.

Note that (1.2) and (1.3) form a complete set of four field equations of the one-dimensional theory for the four unknowns $U$, $V$, $S$, and $H$. By eliminating the functions $U$, $V$, and $H$ from (1.2) and (1.3) we arrive at the stress equation for $S$

$$\left( \frac{\partial^2}{\partial x^2} - \frac{1}{c^2} \frac{\partial^2}{\partial t^2} \right) \left( \frac{\partial^2}{\partial t^2} + \kappa^2 \right) S - \frac{\omega^2}{c^2} \frac{\partial^2}{\partial t^2} S = 0,$$

where

$$c = \frac{\langle \Lambda \rangle^{1/2}}{\langle \rho \rangle^{1/2}}, \quad \kappa = \Omega \frac{\langle \Lambda^* \rangle^{1/2}}{\langle \Lambda \rangle^{1/2}},$$

$$\omega = \Omega \left( 1 - \frac{\langle \Lambda^* \rangle}{\langle \Lambda \rangle} \right)^{1/2}, \quad \Omega = \frac{\langle \Lambda h_x^2 \rangle^{1/2}}{\langle \rho h^2 \rangle^{1/2}},$$

$$\langle \Lambda^* \rangle = \langle \Lambda \rangle - \frac{\langle \Lambda h_x \rangle^2}{\langle \Lambda h_x^2 \rangle}.$$  

(1.10)

(1.11)

Clearly, $c$ has the dimension of velocity, and $\Omega$ has the dimension of frequency, that is,

$$[c] = [LT^{-1}], \quad [\Omega] = [\kappa] = [\omega] = [T^{-1}],$$

(1.12)

where $L$ and $T$ stand for the length and time units, respectively; and $[\cdot]$ represents the dimension of a physical quantity.
As a result, for the microperiodic layered semi-space subject to homogeneous initial conditions and a uniform pressure \( s = s(t) \) on its boundary \( x = 0 \), the following pure stress initial boundary value problem can be formulated.

Find a stress field \( S = S(x,t) \) on \([0, \infty) \times [0, \infty)\) that satisfies the field equation

\[
\left( \frac{\partial^2}{\partial x^2} - \frac{1}{c^2} \frac{\partial^2}{\partial t^2} \right) \left( \frac{\partial^2}{\partial t^2} + \kappa^2 \right) S - \frac{\omega^2}{c^2} \frac{\partial^2}{\partial t^2} S = 0 \quad \text{for } x > 0, \ t > 0 \quad (1.13)
\]

subject to the initial conditions

\[
S(x,0) = 0, \ \frac{\partial}{\partial t} S(x,0) = 0, \ \frac{\partial^2}{\partial t^2} S(x,0) = 0, \ \frac{\partial^3}{\partial t^3} S(x,0) = 0, \quad \text{for } x > 0 \quad (1.14)
\]

and the boundary condition

\[
S(0,t) = -s(t) \quad \text{for } t > 0, \quad (1.15)
\]

where \( s = s(t) \) is a prescribed function. Moreover, the function \( S \) and its partial derivatives of a finite order are to vanish as \( x \to \infty \) for every \( t > 0 \).

If a solution \( S \) to the problem (1.13), (1.14), and (1.15) is found, the functions \( H, U, \) and \( V \) are computed from the formulas

\[
H(x,t) = \frac{\langle \Lambda \rangle}{\langle X \rangle} \int_0^t \cos \kappa (t - \tau) \frac{\partial S}{\partial \tau}(x,\tau) d\tau,
\]

\[
U(x,t) = \frac{1}{\langle \rho \rangle} \int_0^t (t - \tau) \frac{\partial S}{\partial x}(x,\tau) d\tau, \quad \text{and} \quad (1.16)
\]

\[
V(x,t) = -\frac{1}{\langle \rho h^2 \rangle} \int_0^t (t - \tau) H(x,\tau) d\tau.
\]

Also, note that the pure stress problem (1.13), (1.14), and (1.15) contains two high frequency parameters \( \kappa \) and \( \omega \), since, by (1.7) and (1.10), we have

\[
\kappa = l^{-1} 0(1), \quad \omega = l^{-1} 0(1), \quad \text{as } l \to 0. \quad (1.17)
\]

2. Uniqueness and Green's function theorem for the pure stress problem

**UNIQUENESS THEOREM.** The pure stress initial boundary value problem (1.13), (1.14), and (1.15) may have at most one solution.

**PROOF.** See [2, Theorem 3.1]. \( \Box \)

**REPRESENTATION THEOREM.** A solution to problem (1.13), (1.14), and (1.15) admits the representation

\[
S(x,t) = \frac{1}{\kappa} \int_0^t \sin \kappa (t - \tau) \Sigma(x,\tau) \ d\tau, \quad (2.1)
\]

where

\[
\Sigma(x,t) = \int_0^t G(x,t-\tau) \left[ \ddot{s}(\tau) + \kappa^2 s(\tau) \right] d\tau \quad (2.2)
\]
and \( G = G(x,t) \) is a Green’s function for the integro-differential problem. Find a function \( G = G(x,t) \) that satisfies the equation

\[
\left( \frac{\partial^2}{\partial x^2} - \frac{1}{c^2} \frac{\partial^2}{\partial t^2} \right) G - \frac{\omega^2}{c^2} \int_0^t \cos \kappa(t - \tau) \frac{\partial G}{\partial \tau}(x, \tau) \, d\tau = 0 \quad \text{for } x \geq 0, \ t \geq 0,
\]  

(2.3)

the initial conditions

\[
G(x,0) = 0, \quad \frac{\partial}{\partial t} G(x,0) = 0, \quad \text{for } x \geq 0,
\]  

(2.4)

the boundary condition

\[
G(0,t) = -\delta(t),
\]  

(2.5)

and vanishing conditions at infinity. In (2.5) \( \delta = \delta(t) \) is the Dirac delta function.

**Proof.** See [2, equations (38)-(42)].

**Green’s function theorem.** (i) A solution to the integro-differential problem (2.3), (2.4), and (2.5) admits the series representation of the Neumann’s type

\[
G(x,t) = -\delta\left(t - \frac{x}{c}\right) - H\left(t - \frac{x}{c}\right) g\left(x,t - \frac{x}{c}\right),
\]  

(2.6)

where \( H = H(t) \) is the Heaviside function

\[
H(t) = \begin{cases} 
1 & \text{for } t > 0, \\
0 & \text{for } t < 0,
\end{cases}
\]

\[
g(x,t) = \sum_{n=1}^{\infty} \frac{(-1)^n}{n!} \left( \frac{x\omega^2}{2c} \right)^n \left[ \cos \kappa t \right]^n + n \sum_{m=1}^{\infty} \frac{(-1)^m}{m!} \left( \frac{\omega^2}{4} \right)^m \\
\times \frac{(n+2m-1)!}{(n+m)!(m-1)!} \left[ t^{m-1} \right] \left( \cos \kappa t \right)^{n+m} \right] \quad \text{for } x \geq 0, \ t \geq 0.
\]  

(2.7)

Here, for arbitrary functions \( a = a(t) \) and \( b = b(t) \) on \([0, \infty)\), the symbol \( \{a\} \{b\} \) represents the convolution product of \( a = a(t) \) and \( b = b(t) \) defined by (see [3])

\[
\{a\} \{b\} = \int_0^t a(t-\tau) b(\tau) \, d\tau \equiv a \ast b.
\]  

(2.8)

In particular, \( \{f\}^n \) represents the \( n \)th convolutional power of a function \( \{f(t)\} \equiv f(t) \).

(ii) The series representation of \( g = g(x,t) \) and its partial derivatives of a finite order converge uniformly for every point \((x,t) \in (0, \infty) \times (0, \infty)\) and for arbitrary finite parameters \( \omega, \kappa, \) and \( c \).

**Proof.** See [2, equations (43)-(47)].

It follows from the representation theorem that if \( s(t) = \delta(t) \) then \( S(x,t) \equiv G(x,t) \). Hence, the Green’s function for the pure stress problem represents a transient stress wave in the micropagodic layered elastic semi-space \( x > 0 \) subject to a unit impulsive pressure on its boundary \( x = 0 \).
Also, it follows from (2.6) and (2.7) that the transient stress wave described by the function \( G = G(x,t) \) depends strongly on the layering period \( l \) through the frequency parameters \( \omega \) and \( \kappa \) which become large as \( l \to 0 \) (see (1.17)). In the following we prove that the pure stress problem (1.13), (1.14), and (1.15) can be reduced to a dimensionless form in which the microstructural length is absent. More precisely, we prove the following theorem.

**The scale-independent stress wave theorem.** For a particular system of the length and time units, RAT description of the stress waves in a microperiodic layered elastic semi-space is independent of the layering period.

**Proof.** Let \( l_0 \) and \( t_0 \) denote the length and time units, respectively, defined by

\[
l_0 = \langle \Lambda \rangle^{1/2} \langle \rho \rangle^{1/2} \omega, \quad t_0 = \frac{1}{\omega},
\]

and let \( \xi \) and \( \tau \) denote the dimensionless space and time variables, respectively. Then the governing integro-differential equation (2.3) reduces to the dimensionless form

\[
\left( \frac{\partial^2}{\partial \xi^2} - \frac{\partial^2}{\partial \tau^2} \right) \hat{G}(\xi, \tau) - \int_0^\tau \cos \hat{\kappa}(\tau - u) \frac{\partial \hat{G}}{\partial u}(\xi, u) \, du = 0,
\]

where

\[
\hat{\kappa} = \frac{\langle \Lambda^* \rangle^{1/2}}{[\langle \Lambda \rangle - \langle \Lambda^* \rangle]^{1/2}}
\]

and a stress wave in the semi-space \( \xi \geq 0 \) for every \( \tau \geq 0 \) is represented by the \( l \)-independent formula

\[
\hat{G}(\xi, \tau) = -\delta(\tau - \xi) - H(\tau - \xi) \hat{g}(\xi, \tau - \xi),
\]

where

\[
\hat{g}(\xi, \tau) = \sum_{n=1}^\infty \frac{(-1)^n}{n!} \frac{\xi^n}{2^n} \cos \hat{\kappa} \tau \left[ \sum_{m=1}^{n} \frac{(-1)^m(n + 2m - 1)!}{m!(n + m)!(m - 1)!} \frac{1}{4^m (\tau^m - 1)} \right] \right). \tag{2.13}
\]

This completes the proof of the theorem. \( \square \)

Note that the functions \( \hat{G} \) and \( \hat{g} \) in (2.10), (2.11), (2.12), and (2.13) are dimensionless. In particular, \( \hat{G} = \hat{G}(\xi, \tau) \) represents the dimensionless stress related to the nominal stress \( S(x,t) = G(x,t) \) through the formula

\[
\hat{G} = t_0 G. \tag{2.14}
\]

The dimensionless material parameter \( \hat{\kappa} \) ranges over the semi-infinite interval

\[
0 < \hat{\kappa} < \infty. \tag{2.15}
\]

The stress \( \hat{S} = \hat{G} \) as a function of \( \tau \) at the cross-section \( \xi = 1 \) for \( \hat{\kappa} = 1.5 \) and \( \hat{\kappa} = 2.0 \) are shown in Figures 2.1 and 2.2, respectively. A part of \( \hat{S} \) represented by the Dirac delta function \( -\delta(\tau - 1) \) is not shown in these figures.
3. Dispersion of the harmonic stress waves in a microperiodic layered infinite elastic space

**The Dispersion Theorem.** There are two plane stress waves of the form

\[
\hat{S} = S_0 \exp \left[ i(k\xi - \omega \tau) \right],
\]  

(3.1)
where \( k \) = wave number, \( \omega \) = frequency, \( c = \omega / k \) = velocity, propagating in a micro-periodic layered infinite elastic body with the velocities

\[
c_{1,2}(\lambda; \hat{\kappa}) = \frac{1}{\sqrt{2}} \left\{ \left( 1 + \frac{1 + \hat{\kappa}^2}{4\pi^2} \lambda^2 \right) \pm \left[ \left( 1 + \frac{1 + \hat{\kappa}^2}{4\pi^2} \lambda^2 \right)^2 - \frac{\hat{\kappa}^2 \lambda^2}{\pi^2} \right]^{1/2} \right\}^{1/2}
\]

(3.2)

where \( \lambda = 2\pi / k \) is the length of a wave, \( (S_0 > 0) \). Hence, both these waves are dispersive.
**Proof.** The proof of this theorem is based on the observation that a plane harmonic wave satisfies the governing equation (see (1.9) reduced to the dimensionless form)

\[
\left( \frac{\partial^2}{\partial \xi^2} - \frac{\partial^2}{\partial \tau^2} \right) \left( \frac{\partial^2}{\partial \tau^2} + \hat{k}^2 \right) \hat{S} - \frac{\partial^2}{\partial \tau^2} \hat{S} = 0 \quad \text{for} \ |\xi| < \infty, \ \tau > 0. \tag{3.3}
\]

By substituting \( \hat{S} \) from (3.1) into (3.3) and getting rid of the exponential factor we obtain an algebraic equation for \( c \). It follows then that there are only two physically admissible velocities \( c_1 \) and \( c_2 \) that satisfy the algebraic equation, and these velocities are given by (3.2). This completes the proof of the theorem.

The velocities \( c_1 \) and \( c_2 \) as functions of \( \lambda \) for fixed values of \( \hat{k} \) are shown in Figures 3.1 and 3.2. It follows from these figures that a harmonic stress wave propagating with the velocity \( c_1 \) is almost dispersionless over a range of small wave lengths, while that propagating with the velocity \( c_2 \) is almost dispersionless for large \( \hat{k} \) and \( \lambda \). Otherwise, both these waves are strongly dispersive.

Special Issue on
Intelligent Computational Methods for
Financial Engineering

Call for Papers

As a multidisciplinary field, financial engineering is becoming increasingly important in today’s economic and financial world, especially in areas such as portfolio management, asset valuation and prediction, fraud detection, and credit risk management. For example, in a credit risk context, the recently approved Basel II guidelines advise financial institutions to build comprehensible credit risk models in order to optimize their capital allocation policy. Computational methods are being intensively studied and applied to improve the quality of the financial decisions that need to be made. Until now, computational methods and models are central to the analysis of economic and financial decisions.

However, more and more researchers have found that the financial environment is not ruled by mathematical distributions or statistical models. In such situations, some attempts have also been made to develop financial engineering models using intelligent computing approaches. For example, an artificial neural network (ANN) is a nonparametric estimation technique which does not make any distributional assumptions regarding the underlying asset. Instead, ANN approach develops a model using sets of unknown parameters and lets the optimization routine seek the best fitting parameters to obtain the desired results. The main aim of this special issue is not to merely illustrate the superior performance of a new intelligent computational method, but also to demonstrate how it can be used effectively in a financial engineering environment to improve and facilitate financial decision making. In this sense, the submissions should especially address how the results of estimated computational models (e.g., ANN, support vector machines, evolutionary algorithm, and fuzzy models) can be used to develop intelligent, easy-to-use, and/or comprehensible computational systems (e.g., decision support systems, agent-based system, and web-based systems).

This special issue will include (but not be limited to) the following topics:

- **Computational methods**: artificial intelligence, neural networks, evolutionary algorithms, fuzzy inference, hybrid learning, ensemble learning, cooperative learning, multiagent learning
- **Application fields**: asset valuation and prediction, asset allocation and portfolio selection, bankruptcy prediction, fraud detection, credit risk management
- **Implementation aspects**: decision support systems, expert systems, information systems, intelligent agents, web service, monitoring, deployment, implementation

Authors should follow the Journal of Applied Mathematics and Decision Sciences manuscript format described at the journal site http://www.hindawi.com/journals/jamds/. Prospective authors should submit an electronic copy of their complete manuscript through the journal Manuscript Tracking System at http://mts.hindawi.com/, according to the following timetable:
