EXISTENCE OF WEAK SOLUTIONS FOR A SCALE SIMILARITY MODEL OF THE MOTION OF LARGE EDDIES IN TURBULENT FLOW

MERYEM KAYA

Received 28 January 2003 and in revised form 5 May 2003

In turbulent flow, the normal procedure has been seeking means $\overline{u}$ of the fluid velocity $u$ rather than the velocity itself. In large eddy simulation, we use an averaging operator which allows for the separation of large- and small-length scales in the flow field. The filtered field $\overline{u}$ denotes the eddies of size $O(\delta)$ and larger. Applying local spatial averaging operator with averaging radius $\delta$ to the Navier-Stokes equations gives a new system of equations governing the large scales. However, it has the well-known problem of closure. One approach to the closure problem which arises from averaging the nonlinear term is the use of a scale similarity hypothesis. We consider one such scale similarity model. We prove the existence of weak solutions for the resulting system.

1. Introduction

The turbulent flow of an incompressible fluid is modelled by solution $(u,p)$ of the incompressible Navier-Stokes equations

$$
\begin{align*}
  u_t + \nabla \cdot (uu) - \text{Re}^{-1} \Delta u + \nabla p &= f \quad \text{in } \Omega, \text{ for } 0 < t \leq T, \\
  \nabla \cdot u &= 0 \quad \text{in } \Omega, \text{ for } 0 < t \leq T, \\
  u(x,0) &= u_0(x) \quad \text{in } \Omega, \text{ } u = 0 \text{ on } \partial \Omega, \text{ for } 0 < t \leq T, \\
  \int_{\Omega} p \, dx &= 0,
\end{align*}
$$

(1.1)

where $\Omega \subset \mathbb{R}^d \ (d = 2 \text{ or } 3)$, $u : \Omega \times [0,T] \to \mathbb{R}^d$ is the fluid velocity, $p : \Omega \to \mathbb{R}$ is the fluid pressure, $f(x,t)$ is the (known) body force, $u_0(x)$ is the initial flow field, and Re is the Reynolds number. There are numerous
Existence of weak solutions for a scale similarity model

approaches to the simulation of turbulent flows in practical settings. One of the most promising current approaches is large eddy simulation (LES) in which approximations to local spatial averages of $u$ are calculated. In LES, the filtered quantities and fluctuations are defined as

$$
\overline{u}(x,t) = g_\delta * u = \int_{\mathbb{R}^3} g_\delta(x-x')u(x',t)dx',
$$

$$
u' = u - \overline{u},
$$

where

$$
g_\delta = \delta^{-3}g\left(\frac{x}{\delta}\right)
$$

and $g$ is the filter function of characteristic width $\delta$. Applying the filtering operator to the Navier-Stokes equations gives

$$
\begin{align*}
\overline{u}_t + \nabla \cdot (\overline{u}u) - \text{Re}^{-1} \Delta \overline{u} + \nabla p &= \overline{f}, \\
\nabla \cdot \overline{u} &= 0, \text{ in } \Omega \times (0,T].
\end{align*}
$$

The governing equation (1.4) may be rewritten as

$$
\begin{align*}
\overline{u}_t + \nabla \cdot (\overline{u}u) - \text{Re}^{-1} \Delta \overline{u} + \nabla \overline{p} + \nabla \overline{T} &= \overline{f}, \\
\nabla \cdot \overline{u} &= 0, \text{ in } \Omega \times (0,T],
\end{align*}
$$

where $\overline{T}$ denotes the subgrid tensor defined as

$$
\overline{T} := \overline{uu} - \overline{u} \overline{u}
$$

which must be modelled. In general, the approach to closure in LES, based on the scale similarity hypothesis, was introduced in 1980 by Bardina et al. [1]. The idea of scale similarity can be thought of as a sort of extrapolation from the resolved scales to the unresolved scales. The original Bardina model is given by

$$
\overline{uu} - \overline{uu} \sim \overline{uu} - \overline{uu}.
$$

This model has proved to be highly consistent [11, 12], but stability problems have been reported in various tests of the Bardina model. These have led to various extensions of Bardina model such as the Layton model proposed in [8], the Liu-Meneveau-Katz model [10], Horiuti’s filtered Bardina model [4], and many “mixed” models. In this paper, we consider a model proposed in [8], which is another realization of the idea of scale similarity seeking a clear kinetic energy balance. The model is based on the following three modelling steps and the nonlinear term
is written as [9]

\[ \overline{uu} = \overline{u'u} + \overline{u'u'} + \overline{u'u} + \overline{u'u'} \tag{1.8} \]

**Step 1.** The cross terms are modelled by scale similarity:

\[ \overline{u'u} + \overline{u'u} = \overline{u(u - \overline{u}) + (u - \overline{u})u} = \overline{u(u - \overline{u}) + (u - \overline{u})u} \tag{1.9} \]

**Step 2.** The resolved term \( \overline{u'u} \) is modelled with a Boussinesq-type assumption

\[ \overline{u'u} \sim \overline{u'u} + \text{dissipative mechanism on } O(\delta) \text{ scales}, \tag{1.10} \]

where

\[ \nabla \cdot (\overline{u'u}) \sim \nabla \cdot (\overline{u'u}) - A(\delta)\overline{u}. \tag{1.11} \]

The operator \( A(\delta)w \) takes the general form \( A(\delta)w = R^* \nabla \cdot T_F(Rw) \), where \( R \) is a restriction operator to the finest resolved scales. It is defined by the use of its variational representation

\[ -(A(\delta)w, v) = (\nu_F(\delta)D(w - \overline{w}), D(v - \overline{v})) \tag{1.12} \]

where \( \nu_F(\delta) \) is the fine scale fluctuation coefficient. This is simplified to

\[ A(\delta)w \sim \nabla \cdot (\nu_F(\delta)D(w - \overline{w}) - (w - \overline{w})) \tag{1.13} \]

where \( D(w) := (1/2)(\nabla w + \nabla w^t) \).

**Step 3.** The \( u'u' \) term is modelled by a Boussinesq hypothesis that

\[ u'u' \sim -\nu_T(\delta, u) (\nabla \overline{u} + \nabla \overline{u}^t) \tag{1.14} \]

where \( \nu_T(\delta, \overline{u}) \) is called turbulent viscosity coefficient. Using (1.9), (1.11), and (1.14) in (1.4), the model is written with respect to \( (w, q) \) which denotes the resulting approximation to \( (\overline{u}, \overline{p}) \),

\[ w_t + \nabla \cdot (\overline{w}w) + \nabla \cdot (\overline{w}(w - \overline{w}) + (w - \overline{w}) \overline{w}) - \nabla \cdot (\nu_T(\delta, w)(\nabla w + \nabla w^t)) - \nabla q - Re^{-1} \Delta w - A(\delta)w = f, \quad \nabla \cdot w = 0, \text{ in } \Omega \times (0, T], \tag{1.15} \]
where $w, f : \Omega \times [0, T] \to \mathbb{R}^d$, $q : \Omega \to \mathbb{R}$. Boundary and zero mean conditions must be imposed on (1.15). There are several possibilities for the turbulent viscosity coefficient. The most common ones used in computational practice are a bulk viscosity $\nu_T = \nu_T(\delta)$, the viscosity of [5], $\nu_T = (0.17)\delta |w - \bar{w}|$, and the Smagorinsky model, see [2, 6, 7, 13],

$$\nu_T(\delta, w) = (c_s \delta)^2 |\nabla w + \nabla w'|.$$  \hfill (1.16)

We will assume that $\nu_T = 0$, namely, there is no extra viscosity terms. With (1.16) or $\nu_T = \nu_T(\delta)$, our results can be easily extended. Before starting to prove the existence of weak solution for the model, we will give a proof that the model, given by (1.15), is Galilean invariant. It has been shown that the filtered form of Navier-Stokes equation is Galilean invariant [14]. Thus, it is enough to show that

$$\nabla \cdot (\tilde{T}(w + W)) = \nabla \cdot \tilde{T}(w)$$ \hfill (1.17)

for any constant vector $W$. To this end we will give the following lemma.

**Lemma 1.1.** Consider the model of the subgrid tensor

$$\tilde{T} = \bar{uu} - \bar{u} \bar{u} - \bar{w} \bar{w} + \bar{w}(w - \bar{w}) + (w - \bar{w}) \bar{w}$$

$$- (c_s \delta)^2 |\nabla w + \nabla w'|(\nabla w + \nabla w')$$

$$- \nu_F(\delta)D(w - \bar{w}) - (w - \bar{w}) - \nu_F\nu_F$$

$$= \tilde{T}(w),$$

then $\nabla \cdot \tilde{T}(w + W) = \nabla \cdot \tilde{T}(w)$ for any constant vector $W$.

**Proof.** First we consider

$$\tilde{T}(w + W) = (w + W)(\bar{w} + W) + (w + W)(w + W - (\bar{w} + W))$$

$$+ (w + W - (\bar{w} + W))(\bar{w} + W)$$

$$- (c_s \delta)^2 |\nabla (w + W) + \nabla (w + W)'|(\nabla (w + W) + \nabla (w + W)')$$

$$\tilde{T}(w + W) - (w + W)(w + W).$$

(1.19)
Since $W$ is a constant vector, $\overline{W} = W$, $\overline{W} = W$, $\overline{W}w = W\overline{w}$, and $\overline{wW} = \overline{wW}$. Thus,

$$\tilde{T}(w + W) = \overline{wW} + \overline{w(w - \overline{w})} + (w - \overline{w})\overline{w}$$

$$- (c_\delta \delta)^2 \vert \nabla w + \nabla w' \vert (\nabla w + \nabla w')$$

$$- \nu_F(\delta) \overline{D(w - \overline{w})} - (w - \overline{w})$$

$$- wW + (\overline{w} - w)W + W(\overline{w} - w)$$

$$+ \overline{W}w + (\overline{w} - w)W.$$  \hfill (1.20)

Hence, we have

$$\nabla \cdot \tilde{T}(w + W) = \nabla \cdot \tilde{T}(w) + \nabla \cdot (\overline{w} - w)W + \nabla \cdot (W(\overline{w} - w))$$

$$+ \nabla \cdot ((\overline{w} - \overline{w})W) + \nabla \cdot (W(\overline{w} - \overline{w})).$$  \hfill (1.21)

Since the averaging preserves incompressibility \[14\], that is, $\nabla \cdot w = \nabla \cdot \overline{w} = 0$, so we have

$$\nabla \cdot \tilde{T}(w + W) = \nabla \cdot \tilde{T}(w).$$  \hfill (1.22)

This completes the proof. \hfill \Box

### 2. Existence of solutions

In this section, we consider the question of the existence of weak solutions to the following systems. Thus, we seek $(w, q)$ satisfying

$$w_t + \nabla \cdot (\overline{wW}) + \nabla \cdot (\overline{w(w - \overline{w})} + (w - \overline{w})\overline{w} - \nabla q - \Re^{-1} \Delta w$$

$$- A(\delta)w = f, \quad \nabla \cdot w = 0, \text{ in } \Omega \times (0, T],$$

$$w(x, 0) = g_\delta * u_0(x) \quad \text{in } \Omega,$$  \hfill (2.1)

$$w(x_j + L, t) = w(x_j, t),$$

$$\int_\Omega \overline{u_0} \, dx = 0, \quad \int_\Omega \overline{f} \, dx = 0, \quad \int_\Omega \overline{q} \, dx = 0.$$  \hfill (2.2)

We will begin by giving the definition of weak solution. Let $D(\Omega) = \{ \psi : \psi \in C_0^\infty(\Omega) : \nabla \cdot \psi = 0 \text{ in } \Omega \}$, let $H(\Omega)$ be the completion of $D(\Omega)$ in $L^2(\Omega)$, let $H^1(\Omega)$ be the completion of $D(\Omega)$ in $W^{1,2}(\Omega)$, and let $\psi \in D(\Omega)$.

**Definition 2.1.** Let $u_0 \in H(\Omega)$ and $f \in L^2(\Omega_T)$. A measurable function $w : \Omega_T \rightarrow \mathbb{R}^n$ is a weak solution of the problem (2.1) and (2.2) in $\Omega_T$ if
Existence of weak solutions for a scale similarity model

(a) \( w \in V_T = L^2(0,T; H^1) \cap L^\infty(0,T; H) \);
(b) \( w \) verifies

\[
\int_0^t \left[ -\text{Re}^{-1} (\nabla w, \nabla \psi) + (\overline{w} \overline{w}, \nabla \psi) + (\overline{w}(w - \overline{w}) + (w - \overline{w})\overline{w}, \nabla \overline{\psi}) \\
- \nu_F(\delta)(\mathbb{D}(w - \overline{w}), \mathbb{D}(\psi - \overline{\psi})) \right] ds
= - \int_0^t (f, \psi) ds + (w(t), \psi) - (w_0, \psi),
\]

where, for \( T \in (0, \infty) \), \( \Omega_T = \Omega \times [0,T] \).

Before we prove the existence of weak solutions of (2.1), (2.2), and (2.3), we give the following lemma which is proved in [8]. Here, we will give this proof briefly.

**Lemma 2.2.** Let \( b(u,v,w) \) denote the (nonstandard) trilinear form

\[
b(u,v,w) := \int_{\Omega} \overline{u} \overline{v} : \nabla w + \overline{u}(v - \overline{v}) + (u - \overline{u})\overline{v} : \nabla \overline{w} \, dx.
\]

Suppose that the averaging used in \( L^2(\Omega) \) is selfadjoint and commutes with differentiation, \( w \in L^2(\Omega) \) and \( \nabla w \in L^2(\Omega) \) are periodic with zero mean. Then

\[
I = \int_{\Omega} \nabla \cdot \left[ \overline{w} \overline{w} + \overline{w}(w - \overline{w}) + (w - \overline{w})\overline{w} \right] \cdot w \, dx = 0.
\]

**Proof.** Integration by parts and using the properties of the averaging operator yield

\[
I = \int_{\Omega} \left[ \overline{w} \overline{w} + \overline{w}(w - \overline{w}) + (w - \overline{w})\overline{w} \right] : \nabla w \, dx
= \int_{\Omega} \left[ \overline{w} \overline{w} : \nabla w + \overline{w} \nabla w : \nabla \overline{w} - \overline{w} \overline{w} : \nabla \overline{w} - \overline{w} w : \nabla \overline{w} - \overline{w} w : \nabla \overline{w} \right] \, dx.
\]

An easy index calculation shows that

\[
\int_{\Omega} uv : \nabla w \, dx = \int_{\Omega} u \cdot (\nabla w)v \, dx,
\]
which is the more familiar trilinear form. Making this change gives

\[ I = \int_{\Omega} \left[ \overline{w} \cdot (\nabla w)\overline{w} + \overline{w} \cdot (\nabla \overline{w})w + w \cdot (\nabla \overline{w})\overline{w} - 2\overline{w} \cdot (\nabla \overline{w})\overline{w} \right] dx. \quad (2.9) \]

Since \( \nabla \cdot w = 0 \), the third term vanishes. By the assumption on the averaging process, \( \nabla \cdot \overline{w} = 0 \), the last term vanishes. We use the usual skew-symmetry property to obtain

\[ \int_{\Omega} \overline{w} \cdot (\nabla w)\overline{w} + \overline{w} \cdot (\nabla \overline{w})w = 0. \quad (2.10) \]

Thus \( I = 0 \). \( \square \)

**Theorem 2.3.** Let \( T > 0 \) and let \( \Omega \) be any domain in \( \mathbb{R}^d \). Then, for any given \( u_0 \in L^2(\Omega) \) and \( f \in L^2(\Omega_T) \), there exists at least one weak solution to (2.1), (2.2), and (2.3) in \( \Omega_T \).

**Proof.** We will use the Faedo-Galerkin method following the presentation of Galdi in the Navier-Stokes case [3]. Let \( D(\Omega) = \{ \varphi \in C_0^\infty : \nabla \cdot \varphi = 0 \text{ in } \Omega \} \), let \( H(\Omega) \) be the completion of \( D(\Omega) \) in \( L^2(\Omega) \), let \( H^1(\Omega) \) be the completion of \( D(\Omega) \) in \( W^{1,2}(\Omega) \), and let \( \{ \varphi_r \} \subset D(\Omega) \) be the orthonormal basis of \( H(\Omega) \). We will look for approximating solutions \( v^k \) of problem (2.1), (2.2), and (2.3), which have the form

\[ v^k(x,t) = \sum_{r=1}^{k} c_{kr}(t)\varphi_r(x), \quad k \in \mathbb{N}. \quad (2.11) \]

In (2.1), we set \( w = v^k \); multiply by \( \varphi_r \) and integrate over \( \Omega \) to obtain

\[ \frac{d}{dt} (v^k, \varphi_r) - (\overline{v}^k \overline{v}^k, \nabla \varphi_r) + \text{Re}^{-1} (\nabla v^k, \nabla \varphi_r) + \nu_F (\mathbb{D}(v^k - \overline{v}^k), \mathbb{D}(\varphi_r - \overline{\varphi}_r)) \\
- (\overline{v}^k (v^k - \overline{v}^k) + (v^k - \overline{v}^k) \overline{v}^k, \nabla \overline{\varphi}_r) = (f, \varphi_r). \quad (2.12) \]

Note that since \( \nabla \cdot u = 0 \), it follows that \( \Delta u = 2\nabla \cdot \mathbb{D}(u) \). The symmetry of deformation tensor yields

\[ \frac{1}{2} (\nabla u, \nabla v) = (\mathbb{D}(u), \mathbb{D}(v)). \quad (2.13) \]
Thus, we obtain the following equality:

\[
\frac{d}{dt} (v^k, \psi_r) - (\overline{v}^k \overline{v}^k, \nabla \psi_r) + \text{Re}^{-1} (\nabla v^k, \nabla \psi_r) + \frac{\nu_F(\delta)}{2} (\nabla (v^k - \overline{v}^k), \nabla (\psi_r - \overline{\psi}_r)) - (\overline{v}^k (v^k - \overline{v}^k) + (v^k - \overline{v}^k) \overline{v}^k, \nabla \overline{\psi}_r) = (f, \psi_r).
\]

If we write (2.11) in (2.14), this represents a system of ordinary differential equations of the form

\[
\frac{d}{dt} c_{kr}(t) - \sum_{i,j=1}^{k} c_{ki} c_{kj} \left( (g_0 \ast \psi_i) (g_0 \ast \psi_j), \nabla \psi_r \right) + \text{Re}^{-1} \sum_{i=1}^{k} c_{ki} \left( \nabla \psi_i, \nabla \psi_r \right) + \frac{\nu_F(\delta)}{2} \sum_{j=1}^{k} c_{kj} \left( \nabla (\psi_j - g_0 \ast \psi_j), \nabla (\psi_r - g_0 \ast \psi_r) \right) - \sum_{i=1}^{k} c_{ki} c_{kj} \left[ (g_0 \ast \psi_i) (\psi_j - g_0 \ast \psi_j) + (\psi_j - g_0 \ast \psi_j) (g_0 \ast \psi_i), \nabla (g_0 \ast \psi_r) \right] = (\overline{f}, \psi_r) = \overline{f}_r, \quad r = 1, \ldots, k,
\]

with the initial condition

\[
c_{kr}(0) = c_{0r} = (v_0, \psi_r).
\]

Since \(\overline{f}_r \in L^2(0, T)\) for all \(r = 1, \ldots, k\), from the elementary theory of ordinary differential equations, we know that the problem which is given by (2.15) and (2.16) admits a unique solution \(c_{kr} \in W^{1,2}(0, T_k)\), where \(T_k \leq T\).

Multiplying (2.15) by \(c_{kr}\) and summing over \(r\) from 1 to \(k\), we get

\[
\frac{1}{2} \frac{d}{dt} \|v^k_t\|_2^2 - (\overline{v}^k \overline{v}^k, \nabla v^k) + \frac{\nu_F(\delta)}{2} \|\nabla (v^k - \overline{v}^k)\|_2^2 - (\overline{v}^k (v^k - \overline{v}^k) + (v^k - \overline{v}^k) \overline{v}^k, \nabla \overline{\psi}_r) + \text{Re}^{-1} \|\nabla v^k\|_2^2 = (f, v^k).
\]
We integrate this equality to obtain
\[
\|\nu\|^2_2 + 2 \Re^{-1} \int_0^t \|\nabla \nu\|^2_2 ds - 2 \int_0^t (\overline{\nu} \nabla \nu, \nabla \nu) ds \\
+ \nu_F(\delta) \int_0^t \|\nabla (\nu - \overline{\nu})\|^2_2 ds \\
- 2 \int_0^t (\overline{\nu} (\nu - \overline{\nu}) + (\nu - \overline{\nu}) \overline{\nu}, \nabla \overline{\nu}) ds \\
= 2 \int_0^t (f, \nu) ds + \|v_0\|^2_2
\]
with \(v_0 = v_k(0)\). We consider the third and last terms in the left-hand side of (2.18). We write these two terms in nonstandard trilinear form:
\[
b(\nu, \nu, \nu) = -2 \int_\Omega \left[ \nu \cdot \nabla \nu \nu + \nu \cdot \nabla \nu \nu - \nu \cdot \nabla \nu \nu + \nu \cdot \nabla \nu \nu \right] dx.
\]
From Lemma 2.2, \(I = b(\nu, \nu, \nu) = 0\). In the last equality, we use \(I = 0\), Schwarz inequality, and Poincaré-Friedrichs inequality, and since \(\|v_0\| \leq \|v_0\|\), we obtain
\[
\|\nu\|^2_2 + \Re^{-1} \int_0^t \|\nabla \nu\|^2_2 ds + \nu_F(\delta) \int_0^t \|\nabla (\nu - \overline{\nu})\|^2_2 ds \\
\leq C \Re \int_0^t \|f\|^2_2 ds + \|v_0\|^2_2,
\]
where \(C\) is a constant. Then we easily deduce the following bound:
\[
\|\nu\|^2_2 + \Re^{-1} \int_0^t \|\nabla \nu\|^2_2 ds \leq M \quad \forall t \in [0, T],
\]
with \(M\) independent of \(t\) and \(k\). We will now investigate the properties of convergence of the sequence \(\{\nu_k\}\) when \(k \to \infty\). To this end we begin to show that, for any fixed \(r \in \mathbb{N}\), the sequence of functions
\[
G^r_k(t) \equiv (\nu_k(x, t), q_r)
\]
is uniformly bounded and uniformly continuous in \(t \in [0, T]\). The uniform boundness follows at once from (2.21). To show the uniform continuity, integrating (2.14) with respect to \(t\) from \(s\) to \(t\) and using Schwarz
Existence of weak solutions for a scale similarity model

By the usual skew-symmetry property of this trilinear form, we obtain

\[ b(v^k,v^k,\varphi_r) = \int_{\Omega} \tilde{v}^k \cdot \nabla \varphi_r \tilde{v}^k + \tilde{v}^k \cdot \nabla \tilde{v}^k \varphi_r + v^k \cdot \nabla \tilde{v}^k \varphi_r - 2 \tilde{v}^k \cdot \nabla \varphi_r \tilde{v}^k. \tag{2.26} \]

Using Cauchy-Schwarz inequality and Young inequality for convolutions, we get

\[
\int_s^t |b(v^k,v^k,\varphi_r)| \leq s_1 \max_t \|v^k(x,t)\| \sqrt{t-s} \left( \int_s^t \|\nabla v^k\|^2 \right)^{1/2} \tag{2.28}
\]

\[ + s_2 \max_t \|v^k(x,t)\| \sqrt{t-s} \left( \int_s^t \|\nabla v^k\|^2 \right)^{1/2}, \]
where \( s_1 = \max_{x \in \Omega} |\psi_r(x)| \) and \( s_2 = 4\max_{x \in \Omega} |\bar{\psi}_r(x)| \). Now we use this inequality and triangle inequality in (2.23) to obtain

\[
|G'_k(t) - G'_k(s)| \\
\leq \max_t \|v_k(x,t)\| \sqrt{t-s} \left\{ s_1 \left( \int_s^t \|\nabla v_k\|^2 \right)^{1/2} + s_2 \left( \int_s^t \|\nabla v_k\|^2 \right)^{1/2} \right\} \\
+ \frac{v_F(\delta)}{2} s_3 \sqrt{t-s} \left( \int_s^t \|\nabla v_k\|^2 \right)^{1/2} \\
+ \text{Re}^{-1} \|\nabla \psi_r\| \sqrt{t-s} \left( \int_s^t \|\nabla v_k\|^2 \right)^{1/2} \\
+ \max_{x \in \Omega} \|\nabla \psi_r\| \sqrt{t-s} \left( \int_s^t \|f\|^2 \right)^{1/2} ,
\]

(2.29)

where \( s_3 = 2\|\nabla \psi_r\| \). Because of (2.21), the right-hand side of (2.29) converges to zero uniformly as \( t \to s \). The sequence of functions \( G'_k(t) \) is an equicontinuity. By the Ascoli-Arzelá theorem, from the sequence \( \{G'_k(t)\}_{k \in \mathbb{N}} \), we may then select a subsequence which we continue to denote by \( \{G'_k(t)\}_{k \in \mathbb{N}} \) uniformly converging to a continuous function \( G'(t) \). The selected sequence \( \{G'_k(t)\}_{k \in \mathbb{N}} \) may depend on \( r \). However, using Cantor diagonalization method, we end up with a sequence again denoted by \( \{G'_k(t)\}_{k \in \mathbb{N}} \) converging to \( G' \) for all \( r \in \mathbb{N} \) uniformly in \( t \in [0,T] \). This information, together with (2.21) and the weak compactness of the space \( H \), allows us to infer the existence of \( v(t) \in H(\Omega) \) such that

\[
\lim_{k \to \infty} (v_k(t) - v(t), \psi_r) = 0, \quad \text{uniformly in } t \in [0,T], \forall r \in \mathbb{N},
\]

(2.30)

where \( v_k(t) \) converges weakly in \( L^2 \) to \( v(t) \), uniformly in \( t \in [0,T] \), that is,

\[
\lim_{k \to \infty} (v_k(t) - v(t), u) = 0, \quad \text{uniformly in } t \in [0,T], \forall u \in L^2(\Omega).
\]

(2.31)

In view of (2.21), \( v \in L^\infty(0,T;H(\Omega)) \). Again, from (2.21), by the weak compactness of the space \( L^2(\Omega_T) \),

\[
\lim_{k \to \infty} \int_0^t (\partial_m (v_k - v), w) \, ds = 0 \quad \forall w \in L^2(\Omega_T), \quad m = 1, \ldots, n,
\]

(2.32)

with \( \partial_m = \partial/\partial x_m \) and \( v \in L^2(0,T;H^1(\Omega)) \) [3]. It is shown that (2.30) implies the strong convergence of \( \{v_k\} \) to \( v \) in \( L^2(w \times [0,T]) \) for all \( w \subset \Omega \),
Existence of weak solutions for a scale similarity model

that is,

$$\lim_{k \to \infty} \int_0^T \| v_k(t) - v(t) \|^2_{2,Q} dt = 0 \quad (2.33)$$

in [3], where $Q$ is a cube in $\mathbb{R}^n$. Now, with the help of (2.31), (2.32), and (2.33), we show that $v$ is a weak solution to (2.1) and (2.2). Since we have already proved that $v \in V_T$, it remains to show that $v$ satisfies (2.3).

Integrating (2.14) from $0$ to $t < T$, we find

$$- \text{Re}^{-1} \int_0^t (\nabla v^k, \nabla \psi_r) ds + \int_0^t (\overline{\theta}^k (v^k - \overline{\theta}^k) + (v^k - \overline{\theta}^k) \overline{\psi}_r^k, \nabla \overline{\psi}_r^k) ds$$

$$+ \int_0^t (\overline{\theta}^k \overline{\psi}_r^k, \nabla \psi_r) - \frac{v_r(\delta)}{2} \int_0^t (\nabla (v^k - \overline{\theta}^k), \nabla (\psi_r - \overline{\psi}_r)) ds$$

$$= - \int_0^t \overline{f}(s) ds + (v^k(t), \psi_r) - (v_0, \psi_r). \quad (2.34)$$

Now we consider the second and third terms of the left-hand side of (2.34) by the usual skew-symmetry property, writing

$$b(v^k, v^k, \psi_r)$$

$$= \int_0^t \int_\Omega \left[ - \overline{\theta}^k \cdot \nabla \overline{\theta}^k \psi_r - \overline{\theta}^k \cdot \nabla v^k \psi_r - v^k \cdot \nabla \overline{\theta}^k \psi_r + 2\overline{\theta}^k \cdot \nabla \overline{\theta}^k \psi_r \right] dx. \quad (2.35)$$

From (2.31) and (2.32), we get

$$\lim_{k \to \infty} (v^k(t) - v(t), \psi_r) = 0,$$

$$\lim_{k \to \infty} \int_0^t (\nabla v^k(s) - \nabla v(s), \nabla \psi_r) ds = 0. \quad (2.36)$$

Furthermore, let $Q$ be a cube containing the support of $\psi_r$, then we have

$$\left| \int_0^t \left[ (\overline{\theta}^k \cdot \nabla \overline{\theta}^k, \psi_r) - (\overline{\theta} \cdot \nabla \overline{\theta}, \psi_r) \right] ds \right|$$

$$\leq \left| \int_0^t (\overline{\theta}^k - \overline{\theta}) \cdot \nabla \overline{\theta}^k, \psi_r \right|_Q ds + \left| \int_0^t \overline{\theta} \cdot \nabla (\overline{\theta}^k - \overline{\theta}), \psi_r \right|_Q ds \right|. \quad (2.37)$$

We consider the first term of the right-hand side of (2.37), and using Cauchy-Schwarz inequality, we obtain

$$\left| \int_0^t (\overline{\theta}^k - \overline{\theta}) \cdot \nabla \overline{\theta}^k, \psi_r \right|_Q \leq \int_0^t \| \overline{\theta}^k - \overline{\theta} \| \| \nabla \overline{\theta}^k \| \max_{x \in Q} |\psi_r(x)|. \quad (2.38)$$
Setting $s_1 : \max_{x \in Q} |\psi_r(x)|$ and using (2.21) and Young inequality for convolution, we have

$$\left| \int_0^t ((\overline{v}^k - \overline{v}) \cdot \nabla \overline{v}^k, \psi_r)_{Q} \right| \leq C s_1 M^{1/2} \left( \int_0^t \|v^k - v\|_{L^2(Q)}^2 \right)^{1/2}, \quad (2.39)$$

where $C$ is a constant. Thus, using (2.33), we get

$$\lim_{k \to \infty} \left| \int_0^t ((\overline{v}^k - \overline{v}) \cdot \nabla \overline{v}^k, \psi_r)_{Q} ds \right| = 0. \quad (2.40)$$

We also have

$$\left| \int_0^t (\overline{v} \cdot \nabla (\overline{v}^k - \overline{v}), \psi_r)_{Q} ds \right| \leq \sum_{m=1}^n \left| \int_0^t (\partial_m (\overline{v}^k - \overline{v}), \overline{v}_m \psi_r)_{Q} ds \right|$$

$$\leq \sum_{m=1}^n \left| \int_0^t (\partial_m (v^k - v), g_\delta * ((g_\delta * v_m) \psi_r))_{Q} ds \right|,$$

and since $g_\delta * ((g_\delta * v_i) \psi_r) \in L^2(\Omega_T)$, (2.32) implies that

$$\lim_{k \to \infty} \left| \int_0^t (\overline{v} \cdot \nabla (\overline{v}^k - \overline{v}), \psi_r)_{Q} ds \right| = 0. \quad (2.42)$$

Relations (2.40) and (2.42) yield

$$\lim_{k \to \infty} \left| \int_0^t ((\overline{v}^k \cdot \nabla \overline{v}^k, \psi_r) - (\overline{v} \cdot \nabla \overline{v}, \psi_r)) ds \right| = 0. \quad (2.43)$$

Now we consider the second term of $b(v^k, v^k, \psi_r)$ which is given by (2.35). Again let $Q$ be a cube containing the support of $\psi_r$, then we have

$$\left| \int_0^t ((\overline{v}^k \cdot \nabla v^k, \overline{\psi}_r) - (\overline{v} \cdot \nabla v, \overline{\psi}_r)) ds \right|$$

$$\leq \left| \int_0^t ((\overline{v}^k - \overline{v}) \cdot \nabla v^k, \overline{\psi}_r)_{Q} ds \right| + \left| \int_0^t (\overline{v} \cdot \nabla (v^k - v), \overline{\psi}_r)_{Q} ds \right|. \quad (2.44)$$
Existence of weak solutions for a scale similarity model

We use Cauchy-Schwarz inequality and the first term of the right-hand side of (2.44) to obtain

\[
\left| \int_0^t \left( (\bar{v}^k - \bar{v}) \cdot \nabla v^k, \bar{\psi}_r \right)_Q ds \right| \\
\leq s_2 \left( \int_0^t \| \bar{v}^k - \bar{v} \|_{L^2,Q}^2 ds \right)^{1/2} \left( \int_0^t \| \nabla v^k \|_{L^2,Q}^2 ds \right)^{1/2}.
\]  

(2.45)

Using (2.21) and Young inequality, we get

\[
\left| \int_0^t \left( (\bar{v}^k - \bar{v}) \cdot \nabla v^k, \bar{\psi}_r \right)_Q ds \right| \leq C s_2 M^{1/2} \left( \int_0^t \| v^k - v \|_{L^2,Q}^2 ds \right)^{1/2}.
\]  

(2.46)

Thus, using (2.33), we obtain

\[
\lim_{k \to \infty} \left| \int_0^t \left( (\bar{v}^k - \bar{v}) \cdot \nabla v^k, \bar{\psi}_r \right)_Q ds \right| = 0.
\]  

(2.47)

Now we consider the second term of the right-hand side of (2.44); we write

\[
\left| \int_0^t \left( (\bar{v}^k - \bar{v}) \cdot \nabla v^k, \bar{\psi}_r \right)_Q ds \right| \leq \sum_{m=1}^n \left| \int_0^t \left( \partial_m (v^k - v), \bar{\psi}_m \right)_Q ds \right|
\]  

(2.48)

and since \( \bar{\psi}_m \in L^2(\Omega_T) \), (2.32) implies

\[
\lim_{k \to \infty} \left| \int_0^t \left( (\bar{v}^k - \bar{v}) \cdot \nabla v^k, \bar{\psi}_r \right)_Q ds \right| = 0.
\]  

(2.49)

Relations (2.47) and (2.49) yield

\[
\lim_{k \to \infty} \left| \int_0^t \left( (\bar{v}^k \cdot \nabla v^k, \bar{\psi}_r \right) - (\bar{v} \cdot \nabla v, \bar{\psi}_r) \right)_Q ds \right| = 0.
\]  

(2.50)

Similarly we consider the third term of \( b(v^k, v^k, \psi) \) which is given by (2.35); we write

\[
\left| \int_0^t \left( (v^k \cdot \nabla v^k, \bar{\psi}_r \right) - (v \cdot \nabla v, \bar{\psi}_r) \right)_Q ds \right| \\
\leq \left| \int_0^t \left( (v^k - v) \cdot \nabla v^k, \bar{\psi}_r \right)_Q ds \right| + \left| \int_0^t (v \cdot \nabla (\bar{v}^k - \bar{v}), \bar{\psi}_r)_Q ds \right|.
\]  

(2.51)
Again using Cauchy-Schwarz inequality, Young inequality, and (2.21) in the first term of the right-hand side of (2.51), we get

\[
\left| \int_0^t ((v^k - v) \cdot \nabla \overline{v}^k, \overline{q}_r)_{Q} ds \right| \leq C s_2 M^{1/2} \left( \int_0^t \|v^k - v\|_{L^2(\Omega)}^2 ds \right)^{1/2}. \tag{2.52}
\]

Using (2.33), we get

\[
\lim_{k \to \infty} \left| \int_0^t ((v^k - v) \cdot \nabla \overline{v}^k, \overline{q}_r)_{Q} ds \right| = 0. \tag{2.53}
\]

Now we consider the second term of the right-hand side of (2.51)

\[
\left| \int_0^t (v \cdot \nabla (\overline{v}^k - \overline{v}), \overline{q}_r)_{Q} ds \right| \leq \sum_{m=1}^n \left| \int_0^t \partial_m (\overline{v}^k - \overline{v}), v_m \overline{q}_r \right|_{Q} ds \right|. \tag{2.54}
\]

We use the properties of convolutions to obtain

\[
\left| \int_0^t (v \cdot \nabla (\overline{v}^k - \overline{v}), \overline{q}_r)_{Q} ds \right| \leq \sum_{m=1}^n \left| \int_0^t \partial_m (\overline{v}^k - \overline{v}), g_\delta * (v_m \overline{q}_r)_{Q} ds \right|. \tag{2.55}
\]

Since \( g_\delta * (v_m \overline{q}_r) \in L^2(\Omega_T), (2.32) \) implies

\[
\lim_{k \to \infty} \left| \int_0^t (v \cdot \nabla (\overline{v}^k - \overline{v}), \overline{q}_r)_{Q} ds \right| = 0. \tag{2.56}
\]

Relations (2.53) and (2.56) yield

\[
\lim_{k \to \infty} \left| \int_0^t [(v^k \cdot \nabla \overline{v}^k, \overline{q}_r) - (v \cdot \nabla \overline{v}, \overline{q}_r)] ds \right| = 0. \tag{2.57}
\]

Now we consider the last term of \( b(v^k, v^k, q_r) \) which is given by (2.35). Again we can write

\[
\left| \int_0^t [(\overline{v}^k \cdot \nabla \overline{v}^k, \overline{q}_r) - (\overline{v} \cdot \nabla \overline{v}, \overline{q}_r)] ds \right|
\leq \left| \int_0^t ((\overline{v}^k - \overline{v}) \cdot \nabla \overline{v}^k, \overline{q}_r)_{Q} ds \right| + \left| \int_0^t (\overline{v} \cdot \nabla (\overline{v}^k - \overline{v}), \overline{q}_r)_{Q} ds \right|. \tag{2.58}
\]

Similarly, using Cauchy-Schwarz inequality, Young inequality, (2.21), and (2.33) in the first term of the right-hand side of (2.58), we get

\[
\lim_{k \to \infty} \left| \int_0^t ((\overline{v}^k - \overline{v}) \cdot \nabla \overline{v}^k, \overline{q}_r)_{Q} ds \right| = 0. \tag{2.59}
\]
Besides, we get the following inequality for the second term of (2.58):

$$\left| \int_0^t (\bar{v} \cdot \nabla (\bar{v}^k - \bar{v}), \bar{\psi}_r)_{Q} ds \right| \leq \sum_{m=1}^{n} \left| \int_0^t (\partial_m (\bar{v}^k - \bar{v}), \bar{\psi}_r)_{Q} ds \right|. \quad (2.60)$$

From the properties of convolution, we write

$$\left| \int_0^t (\bar{v} \cdot \nabla (\bar{v}^k - \bar{v}), \bar{\psi}_r)_{Q} ds \right| \leq \sum_{m=1}^{n} \left| \int_0^t (\partial_m (\bar{v}^k - \bar{v}), g_{\delta} * (\bar{\psi}_r)_{Q}) ds \right|. \quad (2.61)$$

Since $g_{\delta} * (\bar{\psi}_r)_{Q} \in L^2(\Omega_T)$, and from (2.32), we obtain

$$\lim_{k \to \infty} \left| \int_0^t (\bar{v} \cdot \nabla (\bar{v}^k - \bar{v}), \bar{\psi}_r)_{Q} ds \right| = 0. \quad (2.62)$$

Thus, relations (2.59) and (2.62) yield

$$\lim_{k \to \infty} \left| \int_0^t \left[ (\bar{v}^k \cdot \nabla \bar{v}^k, \bar{\psi}_r) - (\bar{v} \cdot \nabla \bar{\psi}_r) \right] ds \right| = 0. \quad (2.63)$$

Finally, we consider the fourth term of the left-hand side of (2.34). Again let $Q$ be a cube containing the support of $\psi_r$, then we have

$$\left| \int_0^t \left[ (\nabla (v^k - v), \nabla (\psi_r - \bar{\psi}_r)) - (\nabla (\bar{v}^k - \bar{v}), \nabla (\psi_r - \bar{\psi}_r)) \right] ds \right|$$

$$\leq \left| \int_0^t (\nabla (v^k - v), \nabla (\psi_r - \bar{\psi}_r))_{Q} ds \right|$$

$$+ \left| \int_0^t (\nabla (\bar{v}^k - \bar{v}), \nabla (\psi_r - \bar{\psi}_r))_{Q} ds \right|. \quad (2.64)$$

Since $\nabla (\psi_r - \bar{\psi}_r) \in L^2(\Omega_T)$, and using (2.32), we get

$$\lim_{k \to \infty} \left| \int_0^t (\nabla (v^k - v), \nabla (\psi_r - \bar{\psi}_r))_{Q} ds \right| = 0. \quad (2.65)$$

Similarly, since $g_{\delta} \ast \nabla (\psi_r - \bar{\psi}_r) \in L^2(\Omega_T)$, and using (2.32), it gives

$$\lim_{k \to \infty} \left| \int_0^t (\nabla (\bar{v}^k - \bar{v}), \nabla (\psi_r - \bar{\psi}_r))_{Q} ds \right| = 0. \quad (2.66)$$

Using (2.65) and (2.66), we get

$$\lim_{k \to \infty} \left| \int_0^t (\nabla (v^k - \bar{v}^k) - \nabla (v - \bar{v}), \nabla (\psi_r - \bar{\psi}_r)) ds \right| = 0. \quad (2.67)$$
Therefore, taking the limit over \( k \to \infty \) in (2.34) and using (2.36), (2.43), (2.50), (2.57), (2.63), and (2.67), we get

\[
- \text{Re}^{-1} \int_0^t \left( \nabla v, \nabla \psi_r \right) + \int_0^t \left( \bar{v} (v - \bar{v}) + (v - \bar{v}) \bar{v}, \nabla \bar{\psi}_r \right) ds \\
+ \int_0^t \left( \bar{v} \bar{v}, \nabla \psi_r \right) ds - \frac{\nu (\delta)}{2} \int_0^t \left( \nabla (v - \bar{v}), \nabla (\psi_r - \bar{\psi}_r) \right) ds \\
= - \int_0^t \left( f, \psi_r \right) ds + \left( v(t), \psi_r \right) - \left( v_0, \psi_r \right). 
\]

(2.68)

However, from [3, Lemma 2.3], we know that every function \( \psi \in D(\Omega) \) can be uniformly approximated in \( C^2(\overline{\Omega}) \) by functions of the form

\[
\psi_N(x) = \sum_{r=1}^N \gamma_r \psi_r(x), \quad N \in \mathbb{N}, \gamma_r \in \mathbb{R}. 
\]

(2.69)

So we write (2.68) with \( \psi_N \) in place of \( \psi_r \) and we may pass to the limit \( N \to \infty \) in this new relation and use the fact that \( v \in L^2(0,T;H^1) \cap L^\infty(0,T;H) \) to show that \( v \) is a weak solution of (2.1) and (2.2). \( \square \)

Acknowledgments

I would like to thank Prof. Dr. W. J. Layton for this problem, his valuable comments, and several helpful discussions. The research of M. Kaya was conducted during a visit to the University of Pittsburgh.

Call for Papers

Thinking about nonlinearity in engineering areas, up to the 70s, was focused on intentionally built nonlinear parts in order to improve the operational characteristics of a device or system. Keying, saturation, hysteretic phenomena, and dead zones were added to existing devices increasing their behavior diversity and precision. In this context, an intrinsic nonlinearity was treated just as a linear approximation, around equilibrium points.

Inspired on the rediscovering of the richness of nonlinear and chaotic phenomena, engineers started using analytical tools from “Qualitative Theory of Differential Equations,” allowing more precise analysis and synthesis, in order to produce new vital products and services. Bifurcation theory, dynamical systems and chaos started to be part of the mandatory set of tools for design engineers.

This proposed special edition of the Mathematical Problems in Engineering aims to provide a picture of the importance of the bifurcation theory, relating it with nonlinear and chaotic dynamics for natural and engineered systems. Ideas of how this dynamics can be captured through precisely tailored real and numerical experiments and understanding by the combination of specific tools that associate dynamical system theory and geometric tools in a very clever, sophisticated, and at the same time simple and unique analytical environment are the subject of this issue, allowing new methods to design high-precision devices and equipment.

Authors should follow the Mathematical Problems in Engineering manuscript format described at http://www.hindawi.com/journals/mpe/. Prospective authors should submit an electronic copy of their complete manuscript through the journal Manuscript Tracking System at http://mts.hindawi.com/ according to the following timetable:

| Manuscript Due | December 1, 2008 |
| First Round of Reviews | March 1, 2009 |
| Publication Date | June 1, 2009 |
